What are the Sustainable Development Goals?

As a universal call to action, in 2015 the United Nations adopted Sustainable Development Goals (SDGs) as part of the 2030 Agenda for Sustainable Development to be implemented over fifteen years (2015-2030). With 17 objectives and 169 targets, the SDGs have the overall aim to eradicate poverty and other deprivations, introduce strategies that improve health and education, reduce inequality and spur economic growth, while at the same time ensuring environmental protection. To achieve this, a great transformation of the financial, economic and political systems that govern our societies is needed and political commitment and decisive action by all stakeholders is vital. Fully interconnected, the SDGs cover areas as diverse as education, gender equality, responsible consumption and production, and peace, justice and strong institutions. Each SDG has targets that need to be accomplished. Progress on the implementation of these targets is monitored by the Member States through the Voluntary National Reviews and presented at the UN High-level Political Forum on Sustainable Development, the main global forum for reviewing successes, challenges and lessons learned on achieving the 2030 Agenda for Sustainable Development.

How does Earth Sciences contribute to the implementation of the SDG's?

Geoscience, or Earth Science, is the study of the Earth. This includes its surface and the processes that shape it but also its interior and the dynamics that occur beneath the crust. Through the study of the oceans, the atmosphere, rivers and lakes, ice sheets and glaciers, volcanoes and earthquakes, earth science aims to understand how these systems work today, how they operated in the past and to predict how they may behave in the future. The study of geoscience also covers how living things, including humans, interact with the Earth, for example, through the resources we use or how water and ecosystems are interconnected.

The overall aim of the SDGs is to pave the way for a sustainable world and, as it is demonstrated in this booklet, geoscience is at the core of this mission. This discipline has the ability to grasp the complex interconnections between the atmosphere, hydrosphere, cryosphere, biosphere, and lithosphere giving a unique whole-planet perspective of the Earth system. However, it suffers from inherent limitations - incomplete data, lack of experimental control or the inability to make direct measurements - that are related to the fact that geoscience studies a 4.6 billion year old planet where most events occur at temporal scales much larger than the human lifetime. These challenges are very similar to those faced by sustainability science.

It therefore becomes evident that geoscience is paramount for the successful implementation of the Sustainable Development Goals.
With over half of the global population now living in cities, challenges related to transportation, energy supply and access to information and communication technologies are becoming ever more important. Investment in infrastructure and innovation are vital to drive sustainable economic growth and development. Technological progress is also key to finding lasting solutions to both economic and environmental challenges, such as providing new jobs, and promoting energy efficiency and generalised internet access. Technology facilitates data gathering, exploration and exploitation in the geosciences. For example, gravimeters that map the Earth’s gravity field are used in mineral and hydrocarbon exploration; GPS and satellite imaging are used in land mapping; lasers produce highly accurate measurements of fault movement; and sonars provide information on the deep subsurface. Some of these solutions are also applied to make cities safer in early warning systems that inform citizens of an impending hazard or in evaluating seismic vulnerable areas, allowing planners to create better building codes. SDG 9 is dedicated to build resilient infrastructures, promote inclusive and sustainable industrialization and foster innovation.

UNESCO supported the creation of the Seismotectonic Map of Africa. Work is now continuing to accurately assess seismic hazards at a regional scale, identifying and characterizing the major seismic sources on the continent. In this project, the preparation of maps for earthquake hazard and risk assessment for some of the major cities on the continent constitutes an important objective for the social and economic development of Africa.

The International Geoscience Programme (IGCP)

Since 1972, UNESCO, through the International Geoscience Programme (IGCP) and in partnership with the International Union of Geological Sciences (IUGS), has harnessed the intellectual capacity of a worldwide network of geoscientists to lay the foundation for our planet’s future, focusing on responsible and environmental resource extraction, natural hazard resilience and preparedness, and adaptability in an era of changing climate. UNESCO, the only United Nations organization with a mandate to support research and capacity building in geology and geophysics, and its flagship programme, the International Geoscience Programme, actively contribute to society and to the implementation of the Sustainable Development Goals.

IGCP's Contribution to SDG 9

With over half of the global population now living in cities, challenges related to transportation, energy supply and access to information and communication technologies are becoming ever more important. Investment in infrastructure and innovation are vital to drive sustainable economic growth and development. Technological progress is also key to finding lasting solutions to both economic and environmental challenges, such as providing new jobs, and promoting energy efficiency and generalised internet access. Technology facilitates data gathering, exploration and exploitation in the geosciences. For example, gravimeters that map the Earth’s gravity field are used in mineral and hydrocarbon exploration; GPS and satellite imaging are used in land mapping; lasers produce highly accurate measurements of fault movement; and sonars provide information on the deep subsurface. Some of these solutions are also applied to make cities safer in early warning systems that inform citizens of an impending hazard or in evaluating seismic vulnerable areas, allowing planners to create better building codes. SDG 9 is dedicated to build resilient infrastructures, promote inclusive and sustainable industrialization and foster innovation.
